

Group 17 - Sunsets

API 1 features: Ticketmaster's Discovery API

This API is used instead of Meetup grabQL API. Currently able to search for events based on location and key words. Displays events based on search criteria. Resulted events include important information including dates, locations, prices, and descriptions. Includes a "Buy Tickets" button at the bottom of each event card which opens a tab to the corresponding Ticketmaster listing for the event to buy tickets. Also includes a "Route" button next to the "Buy Tickets" option, although not currently implemented so the button is not functional as of now.

API 2 features: Google Maps API

Planned features include map display, map markers, and map type selection. Once the location is searched, the map with the location will be displayed below the header on the left. Once events are searched for, nearby events corresponding to the criteria will be marked with a pin on the map relative to the starting location. These pins will be selectable and when clicked will scroll to its event card and will automatically expand the card. There will also be an option to change the map type between roadmap, satellite, hybrid, and terrain.

Application Interface:

Interface is implemented. Includes a header with the project name on the left and search bar on the right. Below includes a space for the map (currently not implemented), along with a box on the right for inputs and outputs. The input interface has category, search radius, from and to date input, min and max price input, and number of events. The output interface results in event cards with corresponding information. Clicking on an event card expands it, which will display more information such as description, organizer, category, price, and whatever information the event has. Below information includes a button for "Buy Tickets" and "Route", both having an image to follow the usability heuristic 'recognition rather than recall'.

CI/CD and Application Testing:

A .yml file is set up for continuous integration, which automatically runs tests. One file with test functions has been made, which imports directly from the main app.jsx file and tests the features that have been implemented so far, including location updates, switching between displays, and checking if filters are being applied to results. Tests are still being debugged and improved, and more tests will be added once more features are developed.
